INTRODUCTION

- A subset of AI, machine learning, predicts outcomes by analysing data patterns automatically (Mitchell, 1997).
- ML could be a solution in improving the triage system (Elhaj et al., 2023).

OBJECTIVES

To identify the correlation between triage data and ML models, determine the best ML models and to predict triage outcomes based on the Malaysian Triage Scale.

METHODS

- Retrospective cohort study.
- 80% Training and 20% Testing set.
- 312 completed data out of 79891 patients (2019-2023).
- Instrument: Python 3.11, Scikit-learn Python package.

RESULTS & DISCUSSION

- DBP and SBP have a high correlation (R-value 0.61).
- Correlation shows RR has a high impact on triaging to the red zone (Actual_Class_5) with an R-value of 0.36.
- RR has a highly negative impact on SpO₂ (R-value 0.49) and a positive impact on body temperature (R-value 0.32), supported by El-Haj (2023) (R-value 0.47).
- Random Forest, Gradient Boosting and XGBoost are the best ML models with accuracy, precision, recall and F1-score of 100%.
- ROC graph shows that the best three ML models can perfectly distinguish between positive and negative classes involving GZ (fast lane), yellow zone and resus zone with the result of 1.00 (Similar to Gao et al., 2022).

CONCLUSION & RECOMMENDATION

- There are one or more relations between each feature in the triage data, and RF, GBDT, and XGBoost are the best algorithms in developing ML models and predicting triage data accurately.
- Future study to train ML models using a larger dataset.
